

CH3. Single Variable Distribution

Probability mass function (pmf)

Given the range of *discrete* random variable X $\text{supp}(X) \in R$, function $f(x) : R \rightarrow [0, 1]$ is defined as

$$f(x) = \begin{cases} P(X = x), & x \in \text{supp}(X) \\ 0, & x \notin \text{supp}(X) \end{cases} \quad (1)$$

$f(x)$ satisfy:

1. $f(x) > 0, \forall x \in \text{supp}(X)$
2. $\sum_{x \in \text{supp}(X)} f(x) = 1$
3. $P(X \in A) = \sum_{x \in A} f(x), A \in \text{supp}(X)$

And we can say that $f(x)$ is the pmf of X .

Cumulative distribution function (CDF)

$$F(x) = P(X \leq x) = \sum_{x_i \leq x} f(x_i) \quad (2)$$

We can said that $F(x)$ is CDF.

CDF is ‘Cumulative’ distribution function, so it’s a nondecreasing function.

Properties of discrete random variables’ CDF

1. $P(X > a) = 1 - P(X \leq a) = 1 - F(a)$
2. $P(X \geq a) = P(X = a) + P(X > a) = f(a) + 1 - F(a) = 1 - F(a) + f(a)$
3. $P(a < X \leq b) = F(b) - F(a)$
4. $P(a < X < b) = F(b) - f(b) - F(a)$
5. $P(a \leq X \leq b) = F(b) - F(a) + f(a)$
6. $P(a \leq X < b) = F(b) - F(a) + f(a) - f(b)$
7. $\lim_{x \rightarrow -\infty} F(x) = 0, \lim_{x \rightarrow \infty} F(x) = 1$

Probability density function

$$P(a < x < b) = \int_a^b f(x)dx = [F(x)]_a^b = F(b) - F(a) \quad (3)$$

$f(x)$ must satisfy

1. $f(x) > 0, \forall x \in \text{supp}(X)$
2. $\int_{x \in \text{supp}(X)} f(x)dx = 1$

Something important:

- You need to write down the range of x to get full score
- Point probability = 0
- $f(x)$ is height, not probability, so it may > 1

Because

$$\int_a^b f(x)dx = [F(x)]_a^b \quad (4)$$

We can see that

$$f(x) = \frac{\partial F(x)}{\partial x}, \quad F(x) = \int_{-\infty}^x f(u)du \quad (5)$$

Moments of random variables

Expected Value

$$E(x) = \int_a^b xf(x)dx \quad (6)$$

Variance

$$\begin{aligned} \text{Var}(x) &= E\{[x - E(x)]^2\} = E\{x^2 - 2xE(x) - [E(x)]^2\} \\ &= E(x^2) - 2[E(x)]^2 + [E(x)]^2 = E(x^2) - [E(x)]^2 \end{aligned} \quad (7)$$

Quantile

Given $0 < p < 1$, and $F(\cdot)$ is strictly increasing function, if

$$\pi_p = F^{-1}(p) \quad (8)$$

$F(\pi_p) = P(X \leq \pi_p) = p$, then we can say π_p is the p -th quantile of r.v. X

Moment, central moment and standard moment

Given $E(X) = \mu$, $Var(X) = \sigma^2$

1. k - th moment: $E(X^k)$
2. k - th central moment: $\mu_k = E[(X - \mu)^k]$
3. k - th standard moment: $\gamma_k = E(Z_X^k) = E\left[\left(\frac{X-\mu}{\sigma}\right)^k\right] = \frac{E[(X-\mu)^k]}{\sigma^k}$

Moment generating function

$$M_X(t) = E(e^{tX}) = \begin{cases} \sum_x e^{tx} f(x) = \sum_x e^{tx} P(X = x) \\ \int_x e^{tx} f(x) dx \end{cases} \quad (9)$$

To calculate moment by MGF

$$E(X^k) = M_X^{(k)}(t)|_{t=0} \quad (10)$$

Linear combination of MGF

Let $Y = aX + b$

$$M_Y(t) = E(e^{tY}) = E[e^{t(aX+b)}] = E[e^{tb} e^{atX}] = e^{bt} M_X(at) \quad (11)$$

Cumulant generating function

Let $K_X(t) = \ln M_X(t)$

1. $K_X'(t)|_{t=0} = E(X)$
2. $K_X''(t)|_{t=0} = Var(X)$
3. $K_X'''(t)|_{t=0} = E([X - E(X)]^3)$
4. $K_X''''(t)|_{t=0} = E([X - E(X)]^4) - 3[Var(X)]^2$

Jacobian transformation method

Step1. Inverse function: get $x = g^{-1}(y)$, and check if it's 1 to 1.

Step2. Jacobian: calculate $|J| = \left| \frac{\partial g^{-1}(y)}{\partial y} \right|$

Step3. Range: from $supp(X)$ and $g(y)$ get the range of new variable

Step4. Substitute: get $f_Y(y) = f_X[g^{-1}(y)] \times |J|$

Truncated distribution

$$f(x|X \leq a) = \frac{f(x)}{F(a)}, \quad x \leq a \quad (12)$$

$$f(x|X \geq a) = \frac{f(x)}{1 - F(a)}, \quad x \geq a \quad (13)$$

$$f(x|a \leq X \leq b) = \frac{f(x)}{F(b) - F(a)}, \quad a \leq X \leq b \quad (14)$$

Jensen's inequality

if $g(\cdot)$ satisfy $g[(1 - \alpha)x + \alpha y] > (1 - \alpha)g(x) + \alpha g(y)$, it's a strictly concave function. Then

$$E[g(X)] < g[E(X)] \quad (15)$$

if $g(\cdot)$ satisfy $g[(1 - \alpha)x + \alpha y] < (1 - \alpha)g(x) + \alpha g(y)$, it's a strictly convex function. Then

$$E[g(X)] > g[E(X)] \quad (16)$$

if $g(\cdot)$ satisfy $g[(1 - \alpha)x + \alpha y] = (1 - \alpha)g(x) + \alpha g(y)$, it's a linear function. Then

$$E[g(X)] = g[E(X)] \quad (17)$$
